

Basic Knowledge Multi-Stage Water Treatment

Multi-stage water treatment

Water to be treated usually contains several substances with different properties. Consequently, a single basic process is not sufficient to remove these substances. Water treatment plants are therefore generally built in several stages.

From the point of view of environmental protection, plants for treating contaminated groundwater are a classic application example of complex, multi-stage water treatment.

Solids contained in the untreated raw water can cause damage or blockages in plant components (e.g. pipelines and pumps). A mechanical treatment is therefore first applied to remove the solids. If the solids only emerge during the course of the water treatment, such as precipitation and flocculation, mechanical treatment steps are also used in the later stages of water treatment.

Groundwater treatment

Contaminated groundwater is usually treated with the "pump and treat" method. Here, the groundwater is pumped downstream of the contamination zone and purified by conventional processes of water treatment. The purified groundwater is then infiltrated back into the ground upstream of the contamination zone. This creates a circuit into which the groundwater treatment plant is integrated.

Well for contaminated groundwater

Multi-stage groundwater treatment plant

- 1 wells
- 2 inlet of wells
- 3 precipitation (e.g. dissolved iron)
- 4 flocculation
- 5 lamella separator (sedimentation)
- 6 buffer tank
- 7 sand filter
- 8 stripping
- 9 collection tank for sludge
- 10 adsorption on activated carbon
- 11 adsorber for exhaust air from stripping
- 12 collection tank for purified groundwater
- 13 outlet to infiltration wells
- 14 infiltration wells
